ECE 252 Spring 2019 1/52

IPC Motivation

When 2+ processes would like to co-ordinate/exchange data the mechanism is called inter-process communication.

If a process shares data with another process in the system, the operating system will provide some facilities to make this possible.

The motivations for inter-process communication are fairly obvious.

ECE 252 Spring 2019 2/5

IPC Preliminaries

Before proceeding, we need to define some things.

It is the transfer of data from one process to another.

The data being transferred is typically referred to as the message.

The process sending that message is the sender.

The process receiving it will be the receiver.

This terminology may seem (painfully) obvious.

ECE 252 Spring 2019 3/5

ECE 252 Spring 2019 4/52

IPC: What to Send

The processes involved must have some agreement on: What data a message should contain; and The way the data is formatted.

There may be defined standards, e.g., XML.

The processes themselves must be aware the message is in XML format.

How this agreement is made falls outside the purview of the OS.

ECE 252 Spring 2019 5/

Messages: (A)synchronous

Sending and receiving of messages may be either synchronous or asynchronous.

Synchronous Send: the sender sends the message and then is blocked from proceeding until the message is received.

Asynchronous Send: the sender can post the message and then carry on.

Synchronous Receive: the receiver is blocked until it receives a message.

Asynchronous Receive: the receiver is notified there is no message available and continues execution.

ECE 252 Spring 2019 6 / 1

Messages: (A)synchronous

Thus there are four combinations to consider, three of which are common:

- 1 Synchronous send, synchronous receive
- 2 Synchronous send, asynchronous receive
- 3 Asynchronous send, synchronous receive
- 4 Asynchronous send, asynchronous receive

We may also have "acknowledgement" messages.

ECE 252 Spring 2019 7/5

Producer-Consumer Problem

A general paradigm for understanding IPC is known as the *producer-consumer* problem.

The producer creates some information.

The information is later used by the consumer.

Example: the database produces data to be consumed by the shell.

This is a general problem and applicable to client-server situations.

ECE 252 Spring 2019 8 / 52

IPC Implementation Strategies

There are three approaches we will consider on how we can accomplish IPC:

- Shared memory.
- 2 The file system.
- 3 Message passing.

All are quite common.

ECE 252 Spring 2019 9 / 52

ECE 252 Spring 2019 10 / 52

Conceptually, the idea of shared memory is very simple.

A region of memory is designated as being shared with some processes.

Those processes may read and write to that location.

To share an area of memory, the OS must be notified.

ECE 252 Spring 2019 11/5.

Normally, a region of memory is associated with exactly one process (its owner).

That process may read and write that location. Other processes may not.

If a second process attempts to do so, the operating system will intervene and that will be an error.

If a process wants to designate memory as shared, it needs to tell the operating system it is okay.

ECE 252 Spring 2019 12/

The OS needs to know that the memory is referenced by two processes.

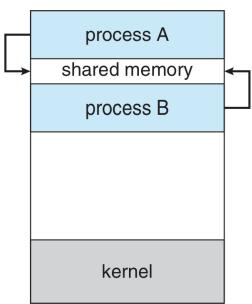

If the first one terminates and is reaped, the memory may still be in use by the second process.

The previously-shared region should not be considered free as long as the second process is still using it.

Once the area of memory is shared, when either process attempts to access it, it is just a normal memory access.

The kernel is only involved in the setup and cleanup of that shared area.

ECE 252 Spring 2019 13/

ECE 252 Spring 2019 14/52

Shared Memory: Risk

When a section of memory is shared, there is the possibility that one process overwrites another's changes.

To prevent this, we need a system of co-ordination.

... A subject we will return to later.

ECE 252 Spring 2019 15/52

File System

ECE 252 Spring 2019 16 / 52

Another way for 2 processes to communicate is through the file system.

Unlike shared memory, messages stored in the file system are persistent.

Can be used if the sender & receiver know nothing about one another.

ECE 252 Spring 2019 17/52

The producer may write to a file in an agreed upon location.

The consumer may read from that same location.

The operating system is still involved because of its role in file creation and manipulation.

ECE 252 Spring 2019 18 / 52

File System: Co-ordination

If one file is being used then we still have the problem of co-ordination.

We can get around this, however, by using multiple files with unique IDs.

Example from a co-op work term: if the producer is generating XML data, it can write in a file in a designated import/ directory.

The consumer program scans the directory, and imports files.

In this case, since one process writes files and another reads them, there is no possibility that one process overwrites the data of another.

If the sender chooses distinct file names, it will not overwrite a message if a second message is created before the receiver picks up the first.

ECE 252 Spring 2019 19 / 52

ECE 252 Spring 2019 20 / 52

Message passing is a service provided by the operating system.

The sender will give the message to the OS and ask that it be delivered to a recipient.

There are two basic operations: sending and receiving.

Messages can be of fixed or variable size.

ECE 252 Spring 2019 21/5.

Our experience with postal mail, or e-mail, suggests that to send a message successfully, the sender needs to indicate where the message should go.

Under *direct communication*, each process that wants to communicate needs to explicitly name the recipient or sender of the communication.

send(A, message) - Send a message to process A. receive(B, message) - Receive a message from process B.

Symmetric addressing.

ECE 252 Spring 2019 22 / 5.

This does not fit our experience with postal mail.

Receiving an item does not require foreknowledge of the sender.

More common: asymmetric addressing.

Sender names the recipient; recipient can receive from anyone.

send(A, message) - Send a message to Process A (unchanged). receive(id, message) - Receive a message from any process; the variable id is set to the sender.

ECE 252 Spring 2019 23/5

In either case, we have to know some identifier for the other processes.

This is not very flexible.

If we want to replace process B with some alternative software...

Change A, recompile it, and reinstall it?

"Fake" the identifier of the new software?

What if the sender will produce the data but is not interested in who receives it?

ECE 252 Spring 2019 24/52

What we would like is *indirect communication* where the messages are sent to mailboxes.

That makes our send and receive functions:

send(M, message) - Send a message to mailbox M. receive(M, message) - Receive a message from mailbox M.

A mailbox may belong to a process or be set up by the OS.

ECE 252 Spring 2019 25 / 5.

If the mailbox belongs to the process:

Anyone can send to this mailbox.

Only the owning process may receive messages from that mailbox.

If the owner process has not started or has terminated, attempting to send to that mailbox will be an error for the sender.

ECE 252 Spring 2019 26/52

If the mailbox is owned by the operating system, it is persistent and independent of any particular process.

There is no conceptual reason preventing an operating system mailbox from belonging to more than one process.

If mailbox M belongs to the operating system and processes P_1 and P_2 have access to it, which process will receive a message sent to M?

ECE 252 Spring 2019 27/5

Two potential solutions:

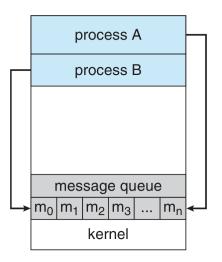

1. Only one process may be the receiver at a time.

 $2.\ \mbox{\ensuremath{\mbox{A}}}$ system for determining whose turn it is.

ECE 252 Spring 2019 28 / 52

Message Queue

A message queue for communication between processes A and B:

ECE 252 Spring 2019 29 / 52

Message Queues

Thus far we have dealt with messages one at a time.

The sender wants to send one message and the receiver wants to receive one message.

If the sender wants to send a second message before the first message is received, the sender will have three choices:

- 1 Wait for the last message to be picked up (block).
- 2 Overwrite the last message (sometimes this is what you want).
- 3 Discard the current message (let the old one remain).

ECE 252 Spring 2019 30 / 52

Message Queue

A queue may alleviate the problem or just "kick the can down the road".

If a queue exists, when sending a message, that message is placed in the queue and when receiving a message, the first message is taken.

If the queue is of (effectively) unlimited size, no problem!

If the queue has a fixed size then the problem is put off but not solved.

The sender can keep adding messages until the queue is full.

If the queue is full, the sender has to face the same choices.

ECE 252 Spring 2019 31/52

Signals are interrupts with a specified ID.

Image Credit: Steven Puetzer/Getty Images

They don't really contain a message.

ECE 252 Spring 2019 32 / 52

Signal: No Message

The fact that a signal contains no message is a limitation that means signals can't be used for every single interprocess communication scenario.

When the fire alarm sounds in a building, you don't need an accompanying voice announcement!

Why?

ECE 252 Spring 2019 33/52

Signal: Preparation

You have previously been informed that when the fire alarm sounds it means you need to exit the building.

Signals: you need to know what to listen for and what's supposed to happen if you want to react accordingly.

ECE 252 Spring 2019 34/52

Programmatic Signals

The appropriate header for including signals is signal.h.

It contains the definitions that let you write SIGKILL instead of having to put an explicit int 9.

Unfortunately there is not always 100% agreement between different implementations about what the higher signal numbers.

ECE 252 Spring 2019 35/52

Programmatic Signals

There are two functions for sending a signal programmatically:

```
int kill( int pid, int signo );
int raise( int signo );
```

Both functions return 0 if they were successful and -1 if they were unsuccessful.

The raise function sends the signal to the current process.

ECE 252 Spring 2019 36/52

Finding the Identity of a Stranger

We need to know the process ID of the recipient.

But how do processes find one another's IDs? Registration!

mysql (a database) server will put its process ID in the file /var/run/mysqld/mysqld.pid.

In that file is just the number of its process ID (e.g., 1494).

Any other communication method will work!

ECE 252 Spring 2019 37 / 52

Why not Function Overload?!

The kill function does different things depending on its first argument.

- pid > 0
- pid == 0
- pid == -1
- pid < -1

ECE 252 Spring 2019 38 / 52

The Null Signal

You can also invoke the kill function with a O argument for the signal.

This is called the null signal.

It does not actually send any signal, but can be used to check if the recipient process exists.

But beware: process IDs are only relatively unique!

ECE 252 Spring 2019 39 / 52

Did You Get My Text?!

A process can only actually deal with a signal when that process is running.

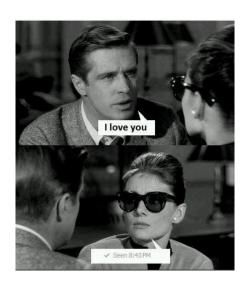

A signal is generated by something, and it is later delivered to the recipient.

But during the time between generation and delivery, we say the signal is pending.

It will be delivered at the first opportunity.

ECE 252 Spring 2019 40 / 52

Awk-ward!

ECE 252 Spring 2019 41/52

Refuse to Listen

For most (but not all) signals, your process can choose to refuse to listen.

This is called blocking signals, and can be done to any with with the exception of SIGKILL and SIGSTOP.

When a signal is blocked, it just remains in the pending state until signals of that type are unblocked.

Blocking is meant to be temporary.

ECE 252 Spring 2019 42/52

Signal Default Actions

Signals have a default action.

The action taken when the signal is delivered is the disposition of the signal.

If you don't explicitly change what happens when the signal arrives, the default (see the table) happens.

But we can change it.

ECE 252 Spring 2019 43/52

Signal Choices

Option 1: Ignore it.

Option 2: Run a signal handler.

Option 3: Run the default option.

We will focus on Option 2 here.

ECE 252 Spring 2019 44/52

MANY WHELPS! HANDLE IT!

If we decide to register a signal handler, the function is:

```
void (*signal( int signo, void (*handler)(int))) (int);
```

signo: Signal number to watch for

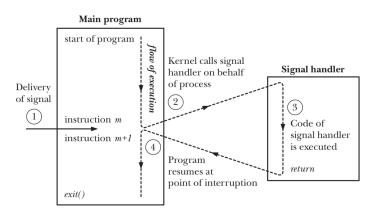

handler: Function to run to handle the signal.

So a sample signal handler would be:

```
void sig_handler( int signal_num ) {
  /* Handle the signal in some way */
}
```

ECE 252 Spring 2019 45 / 52

Signal Handler Workflow

ECE 252 Spring 2019 46 / 52

Tread Carefully!

The content of your signal handler, however, is restricted.

Because the handler deals with an interrupt and runs between two instructions it is important to make sure that the signal handler doesn't mess anything up.

If the signal handler runs in the middle of malloc and the signal handler itself calls malloc it could put the memory management in an invalid state!

We can only use functions that are reentrant.

ECE 252 Spring 2019 47 / 52

Do Some Research

There are tables of what functions are safe to invoke from within a signal handler.

In general what you are looking for is a designation of async-signal safe.

ECE 252 Spring 2019 48 / 52

To block a signal, unblock one, or just find out what the current state is, the function is:

```
int sigprocmask( int how, const sigset_t * set, sigset_t * old_set );
```

The first argument says what we're trying to do here: SIG_BLOCK, SIG_UNBLOCK, SIG_SETMASK.

Third argument: updated to the old values (if provided).

ECE 252 Spring 2019 49 / 52

I am the Mask you wear...

There are some helper functions to fill in the mask:

```
int sigemptyset( sigset_t *set ); /* Initialize an empty sigset_t */
int sigaddset( sigset_t *set, int signal ); /* Add specified signal to set */
int sigfillset( sigset_t *set ); /* Add ALL signals to set */
int sigdelset( sigset_t *set, int signal ); /* Remove specified signal from set */
int sigismember( sigset_t *set, int signal ); /* Returns 1 if true, 0 if false */
```

ECE 252 Spring 2019 50/52

Signal Blocking Example

```
sigset_t set;
sigset_t previous;
sigset_t previous;
sigemptyset( &set ); /* Initialize set */
sigaddset( &set, SIGINT ); /* Add SIGINT to it */
sigprocmask( SIG_BLOCK, &set, &previous ); /* Add SIGINT to the mask */
/* SIGINT is blocked in this section */
sigprocmask( SIG_SETMASK, &previous, NULL ); /* Restore previous mask */
```

ECE 252 Spring 2019 51/52

Waiting for a Page

If you want to pause your program for a bit until the call is interrupted by a signal, there is the function int pause ().

This function always returns -1 and it suspends your program until the signal handler runs.

This can be useful if we really do need to wait for something...

ECE 252 Spring 2019 52/52
